Richard Stallman. Free software: software to be distributed in a manner such that its users receive the freedoms to use, study, distribute and modify that software:

1. The freedom to run the program as you wish, for any purpose
2. The freedom to study how the program works, and change it
3. The freedom to redistribute copies
4. The freedom to distribute copies of your modified versions to others

By "open access" to the STM literature, we mean its free availability on the public internet, permitting any users to read, download, copy, distribute, print, search, or link to the full texts of these articles, crawl them for indexing, pass them as data to software, or use them for any other lawful purpose, without financial, legal, or technical barriers other than those inseparable from gaining access to the internet itself.

Budapest Open Access Initiative. 2002.

Open knowledge is knowledge that one is free to use, reuse, and redistribute without legal, social [economic] or technological restrictions. Open knowledge is a set of principles and methodologies related to the production and distribution of how knowledge works in an *open* manner. Knowledge is interpreted broadly to include data, content and general information.

Open knowledge practices include:

- Clearly articulating an ***open knowledge policy*** and procedure for handling and sharing knowledge products funded and/or produced by your organization.
- Using ***open licensing*** on all knowledge products and implementing open licensing requirements, or recommendations, for funded knowledge products.
- Using ***open repositories***, to store, disseminate and better share funded and published works.
- Using ***Digital Object Identifiers*** (DOIs) to more effectively track the use and readership of shared knowledge products.

Unrestricted access to publications, data and learning materials is backed by a growing number of universities, research centers and funding agencies at national and international level.

International:

- *European Commission. Horizon 2020.*
 - Publications:
 - All beneficiaries are required to deposit and ensure open access.
 - A final peer-reviewed manuscript accepted for publication
 - Institutional repository, Subject-based/thematic repository, Zenodo
 - Research data:
 - Selected Horizon 2020 projects. Projects starting from January 2017 are by default part of the Open Data Pilot
 - Data Management Plan (DMP) required.

National:

- *Spain. Science Law. 2011.*
 - All publications resulting from projects funded by the Spanish government must be deposited in repositories

Institutional:

- *Universitat de València*
 - Courses and learning materials funded by the university to be produced in valencian **MUST** be deposited in the institutional repository.

The early impact of policies was muted: authors are generally not motivated to selfarchive, and in the absence of **monitoring and enforcement** this activity tends to get given a low priority.

This was particularly true for institutional mandates, but even the high-profile funder mandates have seen less than comprehensive compliance to date.

The situation is changing, however, led by funders making compliance a higher priority:

- Bill and Melinda Gates Foundation
- The Research Councils UK policy

- License is important because it encourages sharing. A person interested in a work under a license doesn't have to track down the author and ask for permission to use the work.
- Licensing protects the readers who use an author's works from copyright infringement as long as they are abiding by the author's terms.
- Lots of licenses for any type of content:
 - Software:
 - [GNU General Public License](#) (GPL)
 - Databases:
 - [Open Database License](#), ODbL
 - Other content types, including audio and video:
 - [Creative Commons](#)

Creative Commons explained:

Attribution

You let others copy, distribute, display, and perform your copyrighted work – and derivative works based upon it – but only if they give you credit.

Share Alike

You allow others to distribute derivative works only under a license identical to the license that governs your work.

Non-Commercial

You let others copy, distribute, display, and perform your work – and derivative works based upon it – but for noncommercial purposes only.

No Derivatives

You let others copy, distribute, display, and perform only verbatim copies of your work, not derivative works based upon it.

The licenses may be used in conjunction with each other, for example:

<https://creativecommons.org>

Creative Commons explained:

Manipulating Google Scholar Citations and Google Scholar Metrics: simple, easy and tempting

ABSTRACT

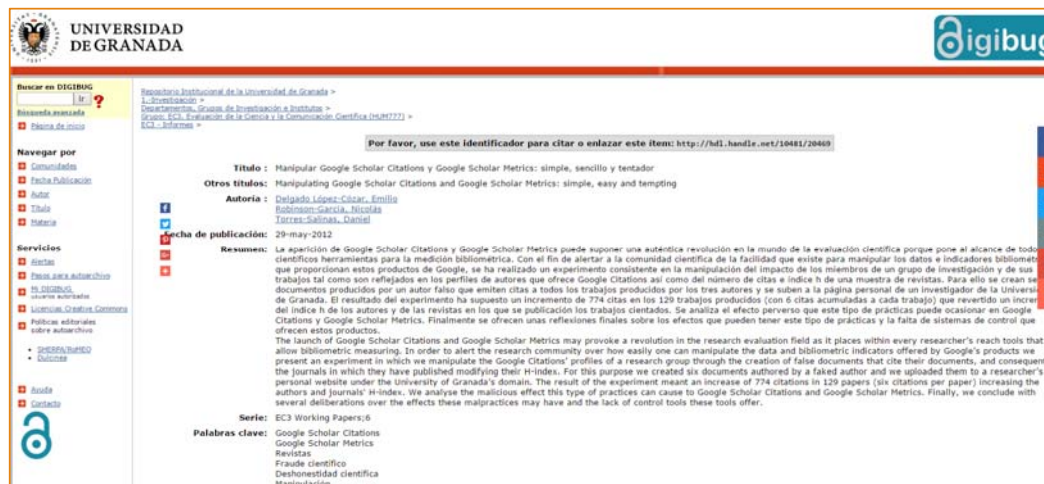

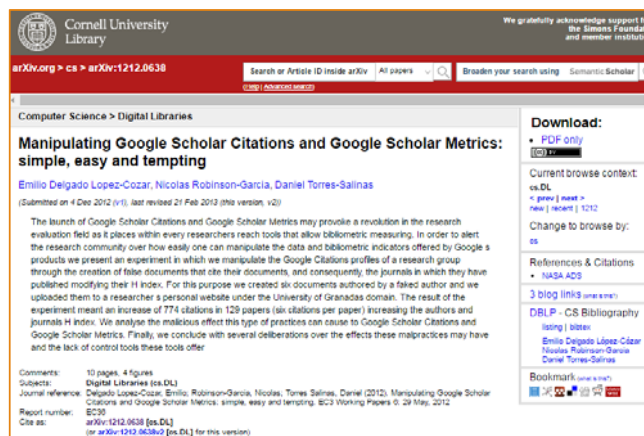

The launch of Google Scholar Citations and Google Scholar Metrics may provoke a revolution in the research evaluation field as it places within every researcher's reach tools that allow bibliometric measuring. In order to alert the research community over how easily one can manipulate the data and bibliometric indicators offered by Google's products we present an experiment in which we manipulate the Google Citations' profiles of a research group through the creation of false documents that cite their documents, and consequently, the journals in which they have published modifying their H-index. For this purpose we created six documents authored by a faked author and we uploaded them to a researcher's personal website under the University of Granada's domain. The result of the experiment meant an increase of 774 citations in 129 papers (six citations per paper) increasing the authors and journals' H-index. We analyse the malicious effect this type of practices can cause to Google Scholar Citations and Google Scholar Metrics. Finally, we conclude with several deliberations over the effects these malpractices may have and the lack of control tools these tools offer.

Manipular Google Scholar Citations y Google Scholar Metrics: simple, sencillo y tentador

La aparición de Google Scholar Citations y Google Scholar Metrics puede suponer una auténtica revolución en la mundo de la evaluación científica porque pone al alcance de todos los científicos herramientas para la medición bibliométrica.

Si en trabajos anteriores hemos apostado abiertamente por la utilización de Google Scholar para la evaluación minimizando los efectos de sesgos y problemas técnicos y metodológicos, con este trabajo queremos alertar a la comunidad científica de la facilidad que existe para manipular los datos e indicadores bibliométricos.

Con el fin de alertar a la comunidad científica de la facilidad que existe para manipular los datos e indicadores bibliométricos que proporcionan estos productos de Google, os presentamos una pequeña nota en la que realizamos un simple y sencillo experimento consistente en la manipulación del impacto de los miembros de un grupo de investigación y de sus trabajos tal como son reflejados en los perfiles de autores que ofrece Google Citations así como del número de citas e índice h de una muestra de revistas.

Independientemente de los problemas técnicos y metodológicos de que adolece la familia Google Scholar, su irrupción supone una auténtica voladura de todos los controles o filtros científicos a los que estaban sometidos los investigadores, sus trabajos y las publicaciones en las que comunicaban sus resultados de investigación, constituyendo un nuevo desafío para el mundo de la evaluación. Desde el momento en que Google Scholar automáticamente rastrea, indiza y vacía cualquier documento de apariencia científica que cuelga de un dominio académico por voluntad de un autor sin sufrir ningún control externo previo (el de los repositorios es solo un filtro técnico que no opera sobre los contenidos) abre la posibilidad a que cualquier persona sin escrúpulos pueda manipular a su entero gusto y beneficio documentos que repercuten directamente sobre la evaluación de su producción e impacto bibliométrico.

Delgado López-Cózar, Emilio; Robinson-García, Nicolás; Torres-Salinas, Daniel (2012). Manipular Google Scholar Citations y Google Scholar Metrics: simple, sencillo y tentador. *EC3 Working Papers* 6, 29 de mayo.
